Getting Started with Docker: how to use it on the Cl

November 26, 2014 by Andrea Colangelo

Containers, and in particular [Docker](#) based ones are **the Big Thing every talks about** and works with these days, and in fact we frequently get que about getting started with Docker. Many people and companies really ta the max and try to do everything in them including tasks which in the p had only considered full VMs for, like untrusted third-party tenants. Pret much everyone uses docker or LXC now to deploy workloads, run CI tes even to have an insulated environment to develop applications with a sp set of libraries and a dedicated configuration. This is especially convenie when you want to share that all across multiple computer or with your colleagues.

So, what is this Docker everybody is talking about and how can you take advantage of it?

What is Docker?

We have a [great course about getting started with Docker](#), and its first lesson is all about the question “What is Docker?”. The course goes in deep detail about this wonderful open source software and the logic behind it.

Nevertheless, Docker is basically a **wrapper around Linux Container**, an old software to create containers on Linux, as you might easily imagine.

Actually, the latest versions of Docker are using a brand new library instead of LXC, but it's a change under the hood with no impact on high-level functionality.

Since it exploits LXC (or this new libcontainer library), Docker containers are built on top of facilities like [cgroups](#) and [namespaces](#) provided by the Linux kernel, so they are not traditional virtual machines and do not require a separate operating system. Instead, they use those kernel's functionality to **completely isolate the application's view of the operating system**. So resources are confined, services are restricted, multiple containers can share the same kernel, but each container can be constrained to only use a defined amount of resources such as CPU, memory and I/O. If you add the fact that a Docker container can start in a handful of milliseconds, you probably now understand how cool the whole thing is.

Using Docker to create and manage containers makes it easier to create distributed systems by allowing multiple applications, worker tasks, and processes to run autonomously on a single physical machine or across a spectrum of virtual machines. And that's why **Docker is finding its heaven in the Cloud**, where a lot of providers, and especially tier-1 players like Amazon,

Google and Microsoft are devoting some of their resources to add compatibility and support for Docker.

Getting started with Docker

Despite the huge complexity hidden under the hood, getting started with Docker is quite easy, also thanks to its Git-style syntax. If you are familiar with VCS, and you probably are if you are interested in Docker, you will find many concepts shared among the two. The base to get a Docker container running is by **starting an image** containing all the files and settings and everything is needed to run the container. I won't spend any more seconds discussing all the details about the Docker syntax and usage, as

well-explained both in the [Getting Started with Docker course](#) I already told you about and in its followup “[Docker: advanced concepts](#)”.

The key factor here is that **it's quite easy to grasp the basic concepts of Docker** and that helped a lot in making the difference about its huge success, as we have just seen, Docker has not reinvented the wheel, rather it wrapped around an existing, solid and well-working technology adding a few features that helped it make the big jump. Nowadays, Docker Inc. is a well-established startup, who [raised more than 40 millions of dollars](#) so far and is seeing a larger and larger ecosystem growing around it. In fact, most Docker hosting services were born to help developers deploy applications and Docker containers on the Internet.

in Docker hosting services

... Indeed, Docker hosting services are among the first companies born in this ecosystem. These are ***aaS services providing virtual machines** to deploy Docker images and/or containers to, sometimes with a good degree of customization of the underlying infrastructure. Sometimes, these services add APIs or other software layers in addition to the standard Docker features making them full-fledged PaaS services.

We already published a [comparison among the 4 most important Docker services](#) in another post, and I really recommend you to read it if you are interested in learning more about them. Sometimes, subtle variations among the various services available can make a huge difference according to your needs, so ensure to read that post thoroughly. Nevertheless, after we published that post, the top players in the Cloud world made their moves to enhance support for Docker on their respective platforms.

Docker support by Amazon, Google, and Microsoft

Amazon announced a brand new service built on top of EC2 during the re:Invent. Actually, everyone was expecting a move there by the giant of Cloud world, given that its closest competitors had announced something similar already. This new service has been called [ECS](#), that is **EC2 Container Service**, and is currently available as a preview. The initial focus of ECS is to address multi-container multi-host clustering, which aligns with customer requirements for high-performance and scale as they move their Docker distributed applications into production. Amazon already had some support for Docker in its [Elastic Beanstalk](#) PaaS service, but this one looks way closer to the Infrastructure level, and we expect it will provide huge flexibility to the needs of the developers. We are looking forward to running an extensive proof of concept about this service, and you can expect a deep review very soon.

... On the other side, Google developed a dedicated support for Docker long before AWS. There is a specific service to help getting started with Docker on GCP, under the name of [Google Container Engine](#). It allows to **deploy an docker container on GCP virtual machines**, paying just for the Google Compute Engine instances that you will provision for your containers and an extra costs. The interesting thing here is that at the core of this Google Container Engine service there is another open source software that Google is actively developing, that is [Kubernetes](#). This is a **cluster manager for containers** that can schedule replicas across a group of node instances. A master instance exposes the Kubernetes API, through which tasks are defined. Kubernetes spawns containers on nodes to handle the defined tasks. Also, the number and type of containers can be dynamically modified according to need. It's a very advanced technology, and I'm looking forward to see Google Container Engine out of the alpha, as they may introduce back

incompatible changes until the stable version will be released. Google is devoting a lot of efforts and resources to this project, and is probably the advanced platform with regard to Docker support.

Microsoft recently added support for Docker containers too. The initial support for Docker on Linux-based Azure VMs has been added in June, but that was just the bare minimum they needed to make Docker available to last month though, they took this thing more seriously, and they announced a stronger commitment in the field. In particular, they announced the open sourcing of Docker Engine for Windows Server, support for the Docker Compose orchestration APIs, and the federation of Docker Hub images in the Azure gallery. Although none of them seems as interesting as the dedicated service provided by Google or Amazon, the fact that even a company like Microsoft is showing such a great interest for Docker confirms how important this software it is and how crucial the container technology has become.

Great post. I have played with Docker since its early beginnings, and this blog post and course are very well done, especially for people that are new to Docker. It was a good r for me :)
